

# (OS1-3) Meld's Experiment

## Aim of experiment

Determination of mass per unit length of a fine wire using meld's experiment

## Apparatus

Electrical Tuning Fork, a Thin Wire or Strings, Scale Ban and Loads

## Theory of experiment

When a periodic force acts on a wire stretched between two fixed points, a transverse wave propagates along the wire with velocity:

$$v = \sqrt{\frac{T}{\mu}}$$

Where,  $T$  is the tension in the wire.

$\mu$  is the mass per unit length of the wire.

The generated wave will be reflected at both fixed points and the incident and reflected waves combine to produce a resultant motion. If the frequency of the fork is equal to one of the natural frequencies of the wire, a state of resonance takes place and the wire shows a stationary wave with a node at each fixed point and one or more antinodes between them.

The natural frequency of order  $n$  of the wire is given by:

$$f_n = \frac{v}{\lambda_n} = \frac{1}{\lambda_n} \sqrt{\frac{T}{\mu}} \quad (1)$$

where  $n$  is an integral (1,2,3,...).

For  $n=1$ , the stationary wave has only one loop (one antinode) and the frequency  $f_1$  is called the first or fundamental harmonic frequency.

For  $n=2,3,4...$  the stationary wave has 2, 3, 4,... loops respectively and the corresponding frequencies  $f_2, f_3, f_4, \dots$ , are called the second, third, fourth .... harmonic frequencies.

Since the distance between two modes is equal to half wave length, so:

$$\lambda_n = 2L/n$$

Where  $L$  is the length of the wire between the two fixed points.

Squaring both sides one have:

$$f_n^2 = \frac{1}{\lambda_n^2} \frac{T}{\mu} \quad (2)$$

Or 
$$\lambda_n^2 = \frac{T}{f_n^2 \mu} \quad (3)$$

## Procedures

1. Put a load ( $M$ ) on the pan. The produced tension is:  $T=(M + M')g$  ; where  $M'$  is the mass of the pan and  $g$  is acceleration due to gravity.
2. By properly adjusting the position of the vibrating fork, one can produce stationary or standing waves with well-defined nodes.

3. Measure the distance between two successive nodes; this will give  $\lambda/2$ . This can be done by counting the number of loops along the length ( $L$ ) of the string, then the average value of ( $\lambda$ ) is  $\lambda = 2L/n$ .
4. Increase the value of ( $M$ ) and repeat steps 2 and 3 and find the corresponding value of  $\lambda$ .
5. Repeat steps 1-4 at least three times and find the average,  $\lambda_{av}$ .
6. Tabulate your results
7. Draw a relation between  $\lambda_{av}^2$  and  $M$ ; which gives a straight line whose slope is  $g/(f^2 \mu)$  from which deduce the value of ( $\mu$ ), the mass per unit length of the string.

## Results

| $M(kg)$ | $\lambda_1 (m)$ | $\lambda_1 (m)$ | $\lambda_1 (m)$ | $\lambda_{av} (m)$ | $\lambda_{av}^2 (m)$ |
|---------|-----------------|-----------------|-----------------|--------------------|----------------------|
|         |                 |                 |                 |                    |                      |
|         |                 |                 |                 |                    |                      |
|         |                 |                 |                 |                    |                      |
|         |                 |                 |                 |                    |                      |
|         |                 |                 |                 |                    |                      |
|         |                 |                 |                 |                    |                      |
|         |                 |                 |                 |                    |                      |

$f =$   $50 \text{ Hz}$

Slope =  $m/kg$

$\mu =$   $kg/m$
